Geometry of Simplex Lab

Henry Robbins (Summer 2020)

Objectives

- Understand the geometry of a linear program's feasible region.
- Use isoprofit lines and planes to solve 2D and 3D LPs graphically.
- Identify the most limiting constraint in an iteration of simplex both algebraically and geometrically.
- Identify the geometric features corresponding to dictionaries.
- Describe the geometrical decision made at each iteration of simplex.

Review

Recall, linear programs (LPs) have three main components: decision variables, constraints, and an objective function. The goal of linear programming is to find a **feasible solution** (a solution satisfying every constraint) with the best objective value. The set of feasible solutions form a **feasible region**. In lecture, we learned about isoprofit lines. For every objective value, we can define an isoprofit line. Isoprofit lines have the property that two solutions on the same line have the same objective value and all isoprofit lines are parallel.

In the first part of the lab, we will use a Python package called GILP to solve linear programs graphically. We introduce the package now.

GILP

If you are running this file in a Google Colab Notebook, uncomment the following line and run it. Otherwise, you can ignore it.

```
In [1]: #!pip install gilp
In [2]: # Imports -- don't forget to run this cell
import gilp
import numpy as np
```

This lab uses default LPs built in to GILP. We import them below.

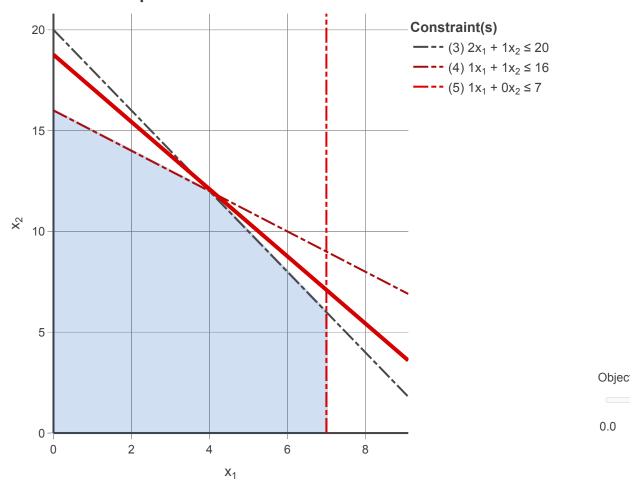

We access the LP examples using gilp.examples.NAME where NAME is the name of the example LP. For example, consider:

$$\begin{array}{ll}
\text{max} & 5x_1 + 3x_2 \\
\text{s.t.} & 2x_1 + 1x_2 \le 20 \\
& 1x_1 + 1x_2 \le 16 \\
& 1x_1 + 0x_2 \le 7 \\
& x_1, x_2 \ge 0
\end{array}$$

This example LP is called ALL_INTEGER_2D_LP. We assign this LP to the variable lp below.

We can visualize this LP using a function called <code>lp_visual()</code> . The function <code>lp_visual()</code> takes an LP and returns a visualization. We then use the <code>.show()</code> function to display the visualization.

Geometric Interpretation of LPs

On the left, you can see a coordinate plane where the x-axis corresponds to the value of x_1 and the y-axis corresponds to the value of x_2 . The region shaded blue is the feasible region. Along the perimeter of the feasible region, you can see points where two edges come to a "corner". You can hover over these **corner points** to see information about them. Only some of the information in the hover box will be relevant for Part I. The first two values of **BFS** represent the values of x_1 and x_2

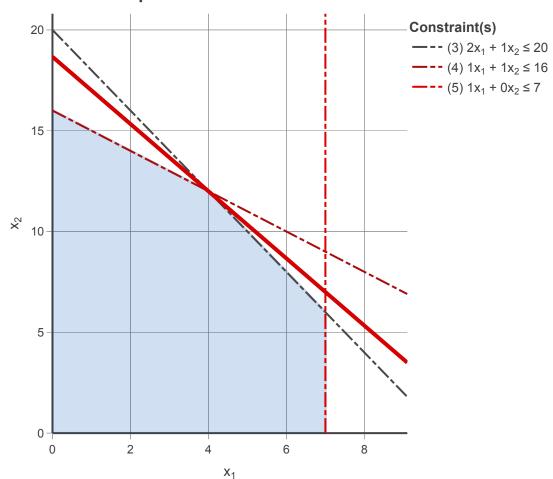

respectively and **Obj** is the objective value. For example, the upper left corner point has solution $x_1=0$ and $x_2=16$ with objective value 48. The dashed lines represent the constraints. You can click on the constraints in the legend to mute and un-mute them. Note this does not alter the LP; it just changes visibility. Lastly, the objective slider allows you to see the isoprofit line for a range of objective values.

Part I: Solving Linear Programs Graphically

Let's use GILP to solve the following LP graphically:

Recall, this LP is called ALL_INTEGER_2D_LP.

Geometric Interpretation of LPs

Object

0.0

Q1: How can you use isoprofit lines to solve LPs graphically?

A: Increase to the maximum obj value while staying in the feasible region

Q2: Use the objective slider to solve this LP graphically. Give an optimal solution and objective value. Argue why it is optimal. (Hint: The objective slider shows the isoprofit line (in red) for some objective value.)

A: Optimal solution is x1=4 x2=12. objective value is 56. We know this is optimal because this is the highest obj value we can obtain while staying in the blue region

Q3: Plug your solution from **Q2** back into the LP and verify that each constraint is satisfied (don't forget non-negativity constraints!) and the objective value is as expected. Show your work.

A:

$$3. 2(4)+12 = 20 20 < =20$$

non negativity 4>=0, 12>=0

Q3.5: Two of the constraints (lines) are satisfied with equality for the optimal solution. Which two are these? How would just knowing that fact allow you find the optimal solution?

A: 3 and 4. Because then we can solve for x1 and x2 just by those two equations, as we know it is equal to the right hand side.

Let's try another! This LP is called DEGENERATE FIN 2D LP.

$$\max 1x_1 + 2x_2$$
s.t.
$$0x_1 + 1x_2 \le 4$$

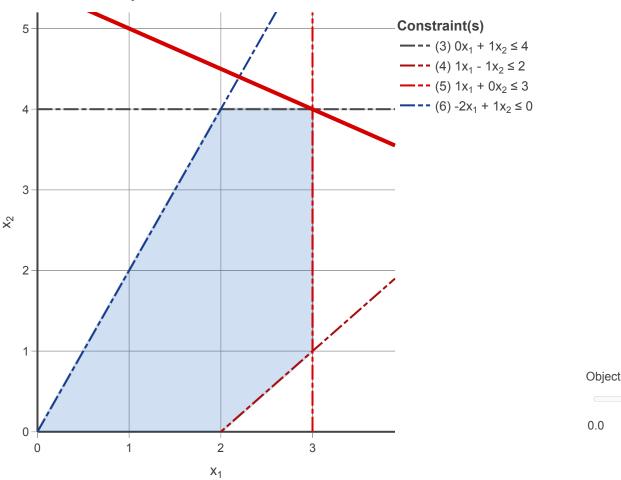

$$1x_1 - 1x_2 \le 2$$

$$1x_1 + 0x_2 \le 3$$

$$-2x_1 + 1x_2 \le 0$$

$$x_1, x_2 \ge 0$$

Q4: Use the objective slider to solve the DEGENERATE_FIN_2D_LP LP graphically. Give an optimal solution and objective value. (Hint: The objective slider shows the isoprofit line (in red) for some objective value.)

A: x1=3, x2=4, obj=11.

You should now be comfortable solving linear programs with two decision variables graphically. In this case, each constraint is a line representing an inequality. These inequalites define a shaded region in the coordinate plane which is our feasible region. Lastly, the isoprofits are parallel lines. To find an optimal solution, we just increase the objective value while the corresponding isoprofit line still intersects the 2D feasible region.

Now, we will try to wrap our head around an LP with three decision variables! Similar to before, we can plot solutions to a 3D LP on a plot with 3 axes. Here, the x-axis corresponds to the value of x_1 and the y-axis corresponds to the value of x_2 as before. Furthermore, the z-axis corresponds to the value of x_3 . Now, constraints are planes representing an inequality. These inequality planes define a 3D shaded region which is our feasible region. The isoprofits are isoprofit planes which are parallel. To find an optimal solution, we just increase the objective value while the corresponding isoprofit plane still intersects the 3D feasible region. Let us look at an example.

This LP is called ALL_INTEGER_3D_LP:

$$\max 1x_1 + 2x_2 + 4x_3$$
s.t.
$$1x_1 + 0x_2 + 0x_3 \le 6$$

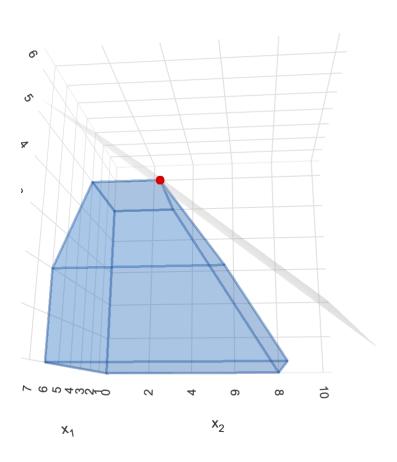

$$1x_1 + 0x_2 + 1x_3 \le 8$$

$$0x_1 + 0x_2 + 1x_3 \le 5$$

$$0x_1 + 1x_2 + 1x_3 \le 8$$

$$x_1, x_2 \ge 0$$

Geometric Interpretation of LPs

Constraint(s)

- (4) $1x_1 + 0x_2 + 0x_3 \le 6$
- (5) $1x_1 + 0x_2 + 1x_3 \le 8$
- (6) $0x_1 + 0x_2 + 1x_3 \le 5$
- $(7) 0x_1 + 1x_2 + 1x_3 \le 8$

Objective

0.0 7.

The 3D feasible region is shown on the left. Hold and drag the mouse to examine it from different angles. Next, click on a constraint to un-mute it. Each constraint is a gray plane in 3D space. Unmute the constraints one by one to see how they define the 3D feasible region. Move the objective slider to see the isoprofit planes. The isoprofit plane is light gray and the intersection with the feasible region is shown in red. Like the 2D visualization, you can hover over corner points to see information about that point.

Q5: Use the objective slider to solve this LP graphically. Give an optimal solution and objective value. (Hint: The objective slider shows the isoprofit plane for some objective value in light gray and

the intersection with the feasible region in red.)

When it comes to LPs with 4 or more decision variables, our graphical approaches fail. We need to find a different way to solve linear programs of this size.

Part II: The Simplex Algorithm for Solving LPs

Dictionary Form LP

First, let's answer some guiding questions that will help to motivate the simplex algorithm.

Q6: Does there exist a unique way to write any given inequality constraint? If so, explain why each constraint can only be written one way. Otherwise, give 2 ways of writing the same inequality constraint.

A: For example with constraint 2x1 + 1x2 <= 20, we can write it as 2x1 <= 20 - x2 or x2 <= 20 - 2x1.

Q7: Consider the following two constraints: $2x_1 + 1x_2 \le 20$ and $2x_1 + 1x_2 + x_3 = 20$ where all x are nonnegative. Are these the same constraint? Why? (This question is tricky!)

A:Yes, because the second one implies the first, as x3 must be nonnegative and it means that 2x1+1x2 has to be <=20.

Q8: Based on your answers to **Q6** and **Q7**, do you think there exists a unique way to write any given LP?

A: No, because theres many ways of writing constraints

You should have found that there are many ways to write some LP. This begs a new question: are some ways of writing an LP harder or easier to solve than others? Consider the following LP:

max
$$56 - 2x_3 - 1x_4$$

s.t. $x_1 = 4 - 1x_3 + 1x_4$
 $x_2 = 12 + 1x_3 - 2x_4$
 $x_5 = 3 + 1x_3 - 1x_4$
 $x_1, x_2, x_3, x_4, x_5 \ge 0$

Q9: Just by looking at this LP, can you give an optimal solution and its objective value. If so, explain what property of the LP allows you to do this. (Hint: Look at the objective function)

A: Yes, opt solution is x3 = 0, x4=0, obj= 56. Because the coefficients of x3 and x4 are negative, we know that by x3=0 and x4=0, we can just subtract nothing from the initial value.

The LP above is the same as ALL_INTEGER_2D_LP just rewritten in a different way! This rewritten form (which we found is easier to solve) was found using the simplex algorithm. At its core, the simplex algorithm strategically rewrites an LP until it is in a form that is "easy" to solve.

The simplex algorithm relies on an LP being in **dictionary form**. Recall the following properties of an LP in dictionary form:

- · All constraints are equality constraints
- · All variables are constrained to be nonnegative
- Each variable only appears on the left-hand side (LHS) or the right-hand side (RHS) of the constraints (not both)
- Each constraint has a unique variable on the LHS
- The objective function is in terms of the variables that appear on the RHS of the constraints only.
- · All constants on the RHS of the constraints are nonnegative

Q10: Rewrite the example LP ALL_INTEGER_2D_LP in dictionary form. Show your steps!

max
$$5x_1 + 3x_2$$

s.t. $2x_1 + 1x_2 \le 20$
 $1x_1 + 1x_2 \le 16$
 $1x_1 + 0x_2 \le 7$
 $x_1, x_2 \ge 0$

A:

1st constraint, subtract 2x1 and 1x2 to the RHS $0 \le -2x1 - 1x2 + 20$ Set RHS to be equal to a variable x3 x3= -2x1 - 1x2 + 20. We know that x3>=0

2nd constraint, subtract 1x1 and 1x2 to RHS $0 \le -x1-x2+16$ Set RHS to be equal to variable x4 x4=-x1-x2+16 We know that x4>=0

3rd constraint, subtract x1 to the RHS 0<= 7-x1 Set RHS to be equal to x5 x5=7-x1 We know that x5>=0

max
$$5x_1 + 3x_2$$

s.t. $x3 = -2x1 - 1x2 + 20$
 $x4 = -x1 - x2 + 16$
 $x5 = 7 - x1$
 $x_1, x_2, x_3, x_4, x_5 \ge 0$

Most Limiting Constraint

Once our LP is in dictionary form, we can run the simplex algorithm! In every iteration of the simplex algorithm, we will take an LP in dictionary form and strategically rewrite it in a new dictionary form. Note: it is important to realize that rewriting the LP **does not** change the LP's feasible region. Let us examine an iteration of simplex on a new LP.

$$\begin{array}{ll} \max & 5x_1 + 3x_2 \\ \text{s.t.} & 1x_1 + 0x_2 \le 4 \\ & 0x_1 + 1x_2 \le 6 \\ & 2x_1 + 1x_2 \le 9 \\ & 3x_1 + 2x_2 \le 15 \\ & x_1, x_2 \ge 0 \end{array}$$

Q11: Is this LP in dictionary form? If not, rewrite this LP in dictionary form.

A: No

max 5x1 + 3x2 st.

x3 = 4 - x1

x4 = 6 - x2

x5 = 9 - 2x1 - 1x2

x6 = 15 - 3x1 - 2x2

x1,x2,x3,x4,x5,x6 >= 0

Q12: Recall from **Q9** how you found a feasible solution (which we argued to be optimal) just by looking at the LP. Using this same stratagy, look at the LP above and give a feasible solution and its objective value for this LP. Describe how you found this feasible solution. Is it optimal? Why?

A: feasible solution ix x1 = 0, x2 = 0 obj=0. Because all the constraints in dictionary form have negative coefficients to the variables, we know that we can just subtract 0 from all constraints feasible values and all values will still be >=0. This is not optimal, as the obj value can be more than 0.

From **Q12** we see that every dictionary form LP has a corresponding feasible solution. Furthermore, there are positive coefficients in the objective function. Hence, we can increase the objective value by increasing the corresponding variable. In our example, both x_1 and x_2 have positive coefficients in the objective function. Let us choose to increase x_1 .

Q13: What do we have to be careful about when increasing x_1 ?

A: That it meets the new constraints in dictionary form

Q14: After choosing a variable to increase, we must determine the most limiting constraint. Let us look at the first constraint $x_3 = 4 - 1x_1 - 0x_2$. How much can x_1 increase? (Hint: what does a dictionary form LP require about the constant on the RHS of constraints?)

A: it can increase by 4.

Q15: Like in **Q14**, determine how much each constraint limits the increase in x_1 and identify the most limiting constraint.

A:

- 1. inc x1 by 4
- 2. no constraints
- 3. increase x1 by 4.5
- 4. increase x1 by 5

most limiting is 1.

If we increase x_1 to 4, note that x_3 will become zero. Earlier, we identified that each dictionary form has a corresponding feasible solution acheived by setting variables on the RHS (and in the objective function) to zero. Hence, since x_3 will become zero, we want to rewrite our LP such that x_3 appears on the RHS. Furthermore, since x_1 is no longer zero, it should now appear on the LHS.

Q16: Rewrite the most limiting constraint $x_3 = 4 - 1x_1 - 0x_2$ such that x_1 appears on the left and x_3 appears on the right.

A: x1 = 4 - x3

Q17: Using substitution, rewrite the LP such that x_3 appears on the RHS and x_1 appears on the LHS. (Hint: Don't forget the rule about which variables can appear in the objective function)

A:

max z = (4-x3)5 + 3x2

z = 20-5x3 + 3x2 st.

x1=4-x3

x4 = 6 - x2

x5 = 9 - 2(4 - x3) - 1x2

x5 = 1 + 2x3 - x2

x6 = 15 - 3(4 - x3) - 2x2

x6=3+3x3-2x2

x1,x2,x3,x4,x5,x6 >= 0

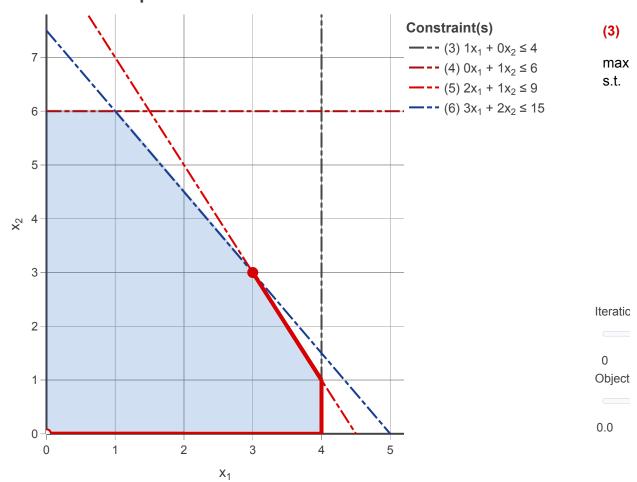

Q18: We have now completed an iteration of simplex! What is the corresponding feasible solution of the new LP?

A: (4,0,0, 6,1,3)

Now that we have seen an iteration of simplex algebraically, let's use GILP to visualize it! The LP example we have been using is called LIMITING_CONSTRAINT_2D_LP. To visualize simplex, we must import a function called simplex_visual().

In [9]: lp = gilp.examples.LIMITING_CONSTRAINT_2D_LP # get the LP example
gilp.simplex_visual(lp, initial_solution=np.array([[0],[0]])).show() # show

Geometric Interpretation of LPs

This visualization is much the same as the previous one but we now have an additional slider which allows you to toggle through iterations of simplex. Furthermore, the corresponding dictionary at every iteration of simplex is shown in the top right. If you toggle between two iterations, you can see the dictionary form for both the previous and next LP at the same time.

Q19: Starting from point (0,0), by how much can you increase x_1 before the point is no longer feasible? Which constraint do you *hit* first? Does this match what you found algebraically?

A: 4, constraint 1. yes it matches what I found algebraically.

Q20: Which variable will be the next increasing variable and why? (Hint: Look at the dictionary form LP at iteration 1)

A: x2 because coefficient is positive

Q21: Visually, which constraint do you think is the most limiting constraint? How much can x_2 increase? Give the corresponding feasible solution and its objective value of the next dictionary form LP. (Hint: hover over the feasible points to see information about them.)

A: x2. x2 can increase by one given constraint 3. Feasible solution is (4,1,0,5,0,1), and obj =23.

Q22: Move the slider to see the next iteration of simplex. Was your guess from **Q21** correct? If not, describe how your guess was wrong.

A: Yes, it was correct.

Q23: Look at the dictionary form LP after the second iteration of simplex. What is the increasing variable? Identify the most limiting constraint graphically and algebraically. Show your work and verify they are the same constraint. In addition, give the next feasible solution and its objective value.

A: Increasing variable is x3.

Algebraically:

- 1. can increase x3 to 4
- 2. no limit on x3
- 3. can increase x3 to 2.5
- 4. can increase x3 to 1. -> most limiting

Graphically the 4th constraint is also the one we hit.

Feasible solution is (3,3,1,3,0,0) and obj =24

Q24: Is the new feasible solution you found in Q23 optimal? (Hint: Look at the dictionary form LP)

A: yes because there are no negative coefficients

Q25: In Q21 and Q23, how did you determine the most limiting constraint graphically?

A: you see which line that prevents you from continuing across the corner edge.

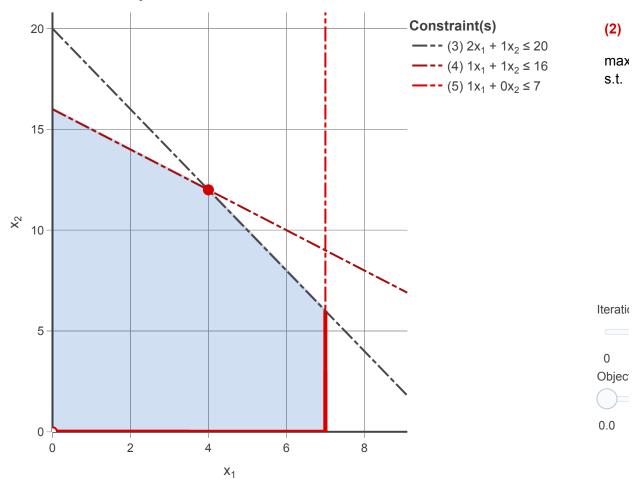

(BONUS): In 2D, we can increase a variable until we hit a 2D line representing the most limiting constraint. What would be the analogous situation in 3D?

A:

Part III: Geometrical Interpretation of the Dictionary

We have seen how the simplex algorithm transforms an LP from one dictionary form to another. Each dictionary form has a corresponding dictionary defined by the variables on the LHS of the constraints. Furthermore, each dictionary form has a corresponding feasible solution obtained by setting all non-dictionary variables to 0 and the dictionary variables to the constants on the RHS. In this section, we will explore the geometric interpretation of a dictionary.

Geometric Interpretation of LPs

Recall, we can hover over the corner points of the feasible region. **BFS** indicates the feasible solution corresponding to that point. For example, (7,0,6,9,0) means $x_1 = 7, x_2 = 0, x_3 = 6, x_4 = 9$, and $x_5 = 0$. **B** gives the indices of the variables "being defined" in that dictionary – that is, the variables that are on the LHS of the constraints. For simplicity, we will just say these variables are *in the dictionary*. For example, if $\mathbf{B} = (1, 3, 4)$, then x_1, x_3 , and x_4 are in the dictionary. Lastly, the objective value at that point is given.

Q26: Hover over the point (7,6) where $x_1 = 7$ and $x_2 = 6$. What is the feasible solution at that point ?

A: (7,6,0,3,0), obj=53.

We have a notion of *slack* for an inequality constraint. Consider the constraint $x_1 \ge 0$. A feasible solution where $x_1 = 7$ has a slack of 7 in this constraint. Consider the constraint $2x_1 + 1x_2 \le 20$. The feasible solution with $x_1 = 7$ and $x_2 = 6$ has a slack of 0 in this constraint.

Q27: What is the slack in constraint $1x_1 + 1x_2 \le 16$ when $x_1 = 7$ and $x_2 = 6$?

A: 3

Q28: Look at the constraint $2x_1 + 1x_2 \le 20$. After rewriting in dictionary form, the constraint is $x_3 = 20 - 2x_1 - 1x_2$. What does x_3 represent?

A: x3 represents the slack of that constraint

Q29: What do you notice about the feasible solution at point (7,6) and the slack in each constraint?

A: They are at the maximum slack for each constraint

It turns out that each decision variable is really a measure of slack in some corresponding constraint!

Q30: If the slack between a constraint and a feasible solution is 0, what does that tell you about the relationship between the feasible solution and constraint geometrically?

A: You can't increase the obj value of the feasible solution because of that constraint, in other words, geometrically that constraint blocks the continued increase of the variable we chose.

Q31: For (7,6), which variables are **not** in the dictionary? For which constraints do they represent the slack? (Hint: The **B** in the hover box gives the indices of the variables in the dicitonary)

A: x3,x5.x3 represents slack of the first constraint in the original question, x5 represents slack of constraint 3 in the original question

Q32: For (7,6), what are the values of the non-dictionary variables? Using what you learned from Q30, what does their value tell you about the feasible solution at (7,6)?

A: non dictionary variables have values of 0. It tells us that first and third constraints in the original question is what is preventing the increase of the objective value for the feasible solution at 7,6.

Q33: Look at some other corner points with this in mind. What do you find?

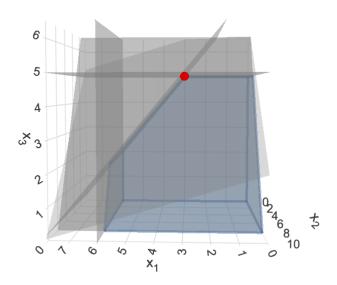

A: slack will be 0 when those constraints are the ones that limit.

Now, let's look at a 3 dimensional LP!

Geometric Interpretation of LPs

Constraint(s)

- $(4) 1x_1 + 0x_2 + 0x_3 \le 6$
- (5) $1x_1 + 0x_2 + 1x_3 \le 8$
- (6) $0x_1 + 0x_2 + 1x_3 \le 5$
- $(7) 0x_1 + 1x_2 + 1x_3 \le 8$

Objective

0.0 7.

Q34: Hover over the point (6,6,2) where $x_1 = 6$, $x_2 = 6$, and $x_3 = 2$. Note which variables are not in the dictionary. Toggle the corresponding constraints on. What do you notice?

A: x4 and x5. Those constraints and the point are intersecting.

Q35: Look at some other corner points and do as you did in Q34. Do you see a similar pattern? Combining what you learned in Q33, what can you say about the relationship between the variables not in the dictionary at some corner point, and the corresponding constraints?

A: yes, corresponding constraints and variables not in the dictionary intersect at the corner point.

Q36: What geometric feature do feasible solutions for a dictionary correspond to?

A: At a corner point

Part IV: Choosing an Increasing Variable

The first step in an iteration of simplex is to choose an increasing variable. Sometimes, there are

multiple options since multiple variables have a positive coefficient in the objective function. Here, we will explore what this decison translates to geometrically.

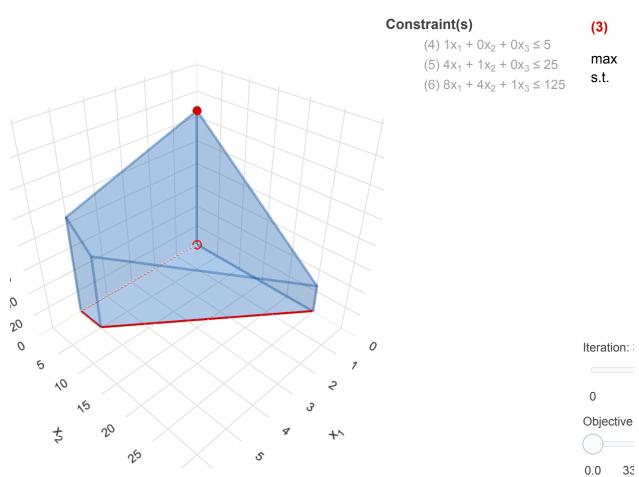

In this section, we will use a special LP commonly referred to as the Klee-Minty Cube.

max
$$4x_1 + 2x_2 + x_3$$

s.t. $x_1 \le 5$
 $4x_1 + x_2 \le 25$
 $8x_1 + 4x_2 + x_3 \le 125$
 $x_1, x_2, x_3 \ge 0$.

Furthermore, we will use an optional parameter called rule for the simplex_visual() function. This rule tells simplex which variable to choose as an increasing variable when there are multiple options.

Geometric Interpretation of LPs

Q37: Use the iteration slider to examine the path of simplex on this LP. What do you notice?

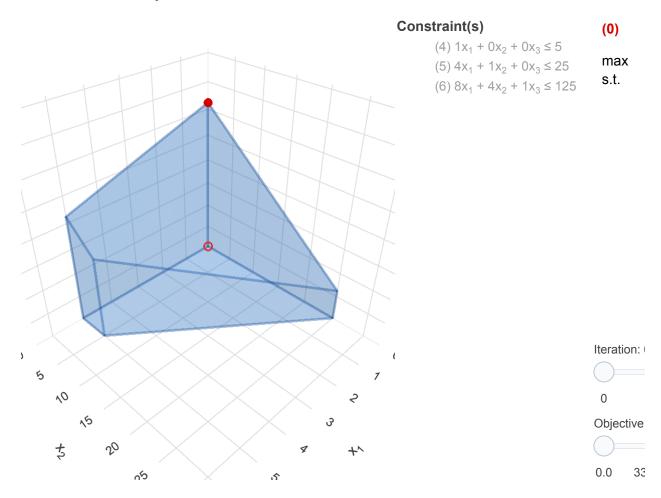

A: It traverses by the next variable that is put into the dictionary

Above, we used a rule proposed by Dantzig. In this rule, the variable with the *largest* positive coefficient in the objective function enters the dictionary. Go through the iterations again to verify this.

Let us consider another rule proposed by Bland, a professor here at Cornell. In his rule, of the variables with positive coefficents in the objective function, the one with the smallest index enters. Let us examine the path of simplex using this rule! Again, look at the dictionary form LP at every iteration.

In [14]: gilp.simplex_visual(klee_minty, rule='bland', initial_solution=np.array([[0

Geometric Interpretation of LPs

Q38: What is the difference between the path of simplex using Dantzig's rule and Bland's rule?

A: Less paths taken in Bland's rule

Can you do any better? By setting rule='manual', you can choose the entering variable explicitly at each simplex iteration.

Q39: Can you do better than 5 iterations? How many paths can you find? (By my count, there are 7)

A: Yes, if you pick x3 first, you only get one iteration

In [17]: gilp.simplex_visual(klee_minty,rule='manual', initial_solution=np.array([[0

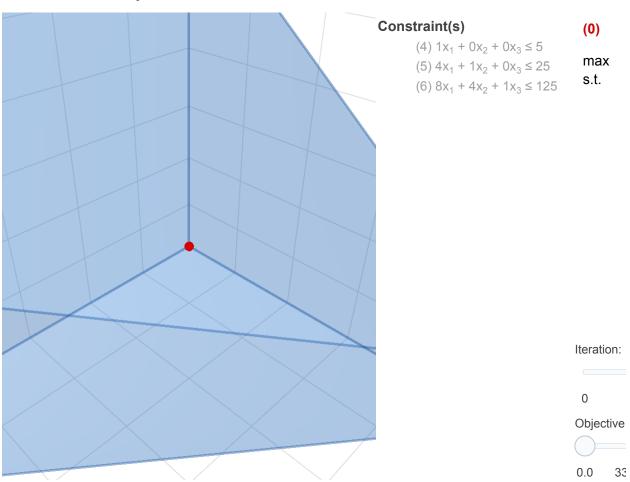

INSTRUCTIONS

At each iteration of simplex, choose one of the variables with a positive coefficent in the objective function. The list of indice for possible variables (also called entering variables) is given.

Pick one of [1, 2, 3]3

s

Geometric Interpretation of LPs

Q40: What does the choice of increasing variable correspond to geometrically?

A: either which axis you traverse or what constraint edge you traverse

Q41: Are there any paths you could visualize taking to the optimal solution that rule='manual_select' prevented you from taking? If yes, give an example and explain why it is not a valid path for simplex to take. (Hint: Look at the objective value after each simplex iteration.)

A: Yes, the paths where objective value would decrease. Its not valid for simplex to take because we are trying to maximize our objective value, so taking a path that decreases the objective value wouldn't make sense

Part V: Creating LPs in GILP (Optional)

We can also create our own LPs! Let us create the following LP.

max
$$3x_1 + 2x_2$$

s.t. $2x_1 + 1x_2 \le 6$
 $0x_1 + 1x_2 \le 2$
 $x_1, x_2 \ge 0$

We will create this LP by specifying 3 arrays of coefficents. We define the NumPy arrays $\, A \,$, $\, b \,$, and $\, c \,$ and then pass them to the $\, LP \,$ class to create the LP.

Let's visualize it!

```
In [ ]: gilp.lp_visual(lp).show()
```

... and solve it!

```
In [ ]: gilp.simplex_visual(lp, initial_solution=np.array([[0],[0]])).show()
```
