Branch & Bound and Knapsack Lab

Objectives

- Preform the branch and bound algorithm
- Apply branch and bound to the knapsack problem
- Understand the geometry of the branch and bound algorithm

Brief description: In this lab, we will try solving an example of a knapsack problem with the branch-and-bound algorithm. We will also see how adding a cutting plane helps in reducing the computation time and effort of the algorithm. Lastly, we will explore the geometry of the branch and bound algorithm.

```
B [1]: # imports -- don't forget to run this cell
import pandas as pd
import gilp
from gilp.visualize import feasible_integer_pts
from ortools.linear_solver import pywraplp as OR
```

Part 1: Branch and Bound Algorithm

Recall that the branch and bound algorithm (in addition to the simplex method) allows us to solve integer programs. Before applying the branch and bound algorithm to the knapsack problem, we will begin by reviewing some core ideas. Furthermore, we will identify a helpful property that will make branch and bound terminate quicker later in the lab!

Q1: What are the different ways a node can be fathomed during the branch and bound algorithm? Describe each.

A:

```
If the LP bound is >= obj function value of our current best feasible
solution, then we don't need to explore that node.
If there's no feasible solution for LP-relaxation, then we do not need to
continue searching for integer solution with these restrictions.
```

Q2: Suppose you have a maximization integer program and you solve its linear program relaxation. What does the LP-relaxation optimal value tell you about the IP optimal value? What if it is a minimization problem?

A:

```
If it is a maximization/minimization problem, LP-relaxation optimal value
gives the upper/lower bound on the optimal value of the integer program.
```

Q3: Assume you have a maximization integer program with all integral coefficents in the objective function. Now, suppose you are running the branch and bound algorithm and come across a node with an optimal value of 44.5. The current incumbent is 44. Can you fathom this node? Why or why not?

A:

```
No, we can not fathom this node because the optimal value found is greater
than the current incumber.
```

Q4: If the optimal solution to the LP relaxation of the original program is integer, then you have found an optimal solution to your integer program. Explain why this is true.

A:

```
An LP optimum is an upper bound on the optimal value of the integer
program.
LP optimal solution is a feasible solution to the IP, and hence the
optimal value for the IP is at least the objective function value of this
solution. Hence, we have equal upper and lower bounds, and so the value of
this solution must be optimal value to the IP, and hence the solution is
optimal.
```

Q5: If the LP is infeasible, then the IP is infeasible. Explain why this is true.

A:

```
Every IP solution is feasible for LP. Therefore if the LP is infeasible,
then the IP is also infeasible
```

The next questions ask about the following branch and bound tree. If the solution was not integral, the fractional x_i that was used to branch is given. If the solution was integral, it is denoted *INT*. In the current iteration of branch and bound, you are looking at the node with the *****.
Q6: Can you determine if the integer program this branch and bound tree is for is a minimization or maximixation problem? If so, which is it?

A:

```
It is for minimization problem.
```

Hint: For **Q7-8**, you can assume integral coefficents in the objective function.

Q7: Is the current node (marked z^*) fathomed? Why or why not? If not, what additional constraints should be imposed for each of the next two nodes?

A:

```
No, the node z* is not fathomed because it is less that the current
integer solution. Additional constraints to be added are x1 <= 0 and x1 >=
1
```

Q8: Consider the nodes under the current node (where $z = 16.3$). What do you know about the optimal value of these nodes? Why?

A:

```
The optimal value of these nodes is at least 16.3
```

Part 2: The Knapsack Problem

In this lab, you will solve an integer program by branch and bound. The integer program to be solved will be a knapsack problem.

Knapsack Problem: We are given a collection of n items, where each item $i = 1, \ldots, n$ has a weight w_i and a value v_i. In addition, there is a given capacity W, and the aim is to select a maximum value subset of items that has a total weight at most W. Note that each item can be brought at most once.

$$
\begin{aligned}
\max \quad & \sum_{i=1}^{n} v_i x_i \\
\text{s.t.} \quad & \sum_{i=1}^{n} w_i x_i \leq W \\
& 0 \leq x_i \leq 1, \text{integer}, i = 1, \ldots, n
\end{aligned}
$$

Consider the following data which we import from a CSV file:

B [2]:
```
data = pd.read_csv('knapsack_data_1.csv', index_col=0)
data
```

Out[2]:

item	value	weight
1	50	10
2	30	12
3	24	10
4	14	7
5	12	6
6	10	7
7	40	30

and $W = 18$.

Q9: Are there any items we can remove from our input to simplify this problem? Why? If so, replace `index` with the item number that can be removed in the code below. Hint: how many of each item could we possibly take?

A:

```
The item 7 can be removed because it is weight is greater than W = 18.
```

B [3]:
```
# TODO: replace index
data = data.drop(7)
```

Q10: If we remove item 7 from the knapsack, it does not change the optimal solution to the integer program. Explain why.

A:

```
Because the solution with item 7 included is infeasible.
```

Q11: Consider removing items i such that $w_i > W$ from a knapsack input. How does the LP relaxation's optimal value change?

A:

```
It does not change the LP relaxation's optimal value
```

In **Q10-11**, you should have found that removing these items removes feasible solutions from the

linear program but does not change the integer program. This is desirable as the gap between the optimal IP and LP values can become smaller. By adding this step, branch and bound may terminate sooner.

Recall that a branch and bound node can be fathomed if its bound is no better than the value of the best feasible integer solution found thus far. Hence, it helps to have a good feasible integer solution as quickly as possible (so that we stop needless work). To do this, we can first try to construct a good feasible integer solution by a reasonable heuristic algorithm before starting to run the branch and bound procedure.

In designing a heuristic for the knapsack problem, it is helpful to think about the value per unit weight for each item. We compute this value in the table below.

```
B [4]:  data['value per unit weight'] = (data['value'] / data['weight']).round(2)
        data
```

Out[4]:

item	value	weight	value per unit weight
1	50	10	5.00
2	30	12	2.50
3	24	10	2.40
4	14	7	2.00
5	12	6	2.00
6	10	7	1.43

Q12: Design a reasonable heuristic for the knapsack problem. Note a heuristic aims to find a decent solution to the problem (but is not necessarily optimal).

A:

```
Order the items in descending order by their value per unit weight. If
adding the item to the solution does meet weight constraint, then x = 1.
If not, skip the node.
```

Q13: Run your heuristic on the data above to compute a good feasible integer solution. Your heuristic should generate a feasible solution with a value of 64 or better. If it does not, try a different heuristic (or talk to your TA!)

A:

```
x1 = x4 = 1 and x2 = x3 = x5 = x6 = x7 = 0, with z = 64.
```

We will now use the branch and bound algorithm to solve this knapsack problem! First, let us define a mathematical model for the linear relaxation of the knapsack problem.

Q14: Complete the model below.

B [8]:
```python
def Knapsack(table, capacity, integer = False):
    """Model for solving the Knapsack problem.

    Args:
        table (pd.DataFrame): A table indexd by items with a column for val
        capcity (int): An integer-capacity for the knapsack
        integer (bool): True if the variables should be integer. False othe
    """
    ITEMS = list(table.index)        # set of items
    v = table.to_dict()['value']     # value for each item
    w = table.to_dict()['weight']    # weight for each item
    W = capacity                     # capacity of the knapsack

    # define model
    m = OR.Solver('knapsack', OR.Solver.CBC_MIXED_INTEGER_PROGRAMMING)

    # decision variables
    x = {}
    for i in ITEMS:
        if integer:
            x[i] = m.IntVar(0, 1, 'x_%d' % (i))
        else:
            x[i] = m.NumVar(0, 1, 'x_%d' % (i))

    # define objective function here
    m.Maximize(sum(v[i]*x[i] for i in ITEMS))

    # TODO: Add a constraint that enforces that weight must not exceed capa
    # recall that we add constraints to the model using m.Add()
    m.Add(sum(w[i]*x[i] for i in ITEMS) <= W)

    return (m, x)  # return the model and the decision variables
```

B [6]:
```python
# You do not need to do anything with this cell but make sure you run it!
def solve(m):
    """Used to solve a model m."""
    m.Solve()

    print('Objective =', m.Objective().Value())
    print('iterations :', m.iterations())
    print('branch-and-bound nodes :',m.nodes())

    return ({var.name() : var.solution_value() for var in m.variables()})
```

We can now create a linear relaxation of our knapsack problem. Now, `m` represents our model and `x` represents our decision variables.

B [9]:
```python
m, x = Knapsack(data, 18)
```

We can use the next line to solve the model and output the solution

B [10]: `solve(m)`

```
Objective = 70.0
iterations : 0
branch-and-bound nodes : 0
```

Out[10]:
```
{'x_1': 1.0,
 'x_2': 0.66666666666666667,
 'x_3': 0.0,
 'x_4': 0.0,
 'x_5': 0.0,
 'x_6': 0.0}
```

Q15: How does this optimal value compare to the value you found using the heuristic integer solution?

A:

```
It is better than the value I found using heuristic integer solution.
```

Q16: Should this node be fathomed? If not, what variable should be branched on and what additional constraints should be imposed for each of the next two nodes?

A:

```
This node should not be fathomed. Variable x2 should be branched with
constraint x2<=0 and x2>=1 imposed for each of the next two nodes.
```

After constructing the linear relaxation model using `Knapsack(data1, 18)` we can add additional constraints. For example, we can add the constraint $x_2 \leq 0$ and solve it as follows:

B [11]:
```
m, x = Knapsack(data, 18)
m.Add(x[2] <= 0)
solve(m)
```

```
Objective = 69.2
iterations : 0
branch-and-bound nodes : 0
```

Out[11]: `{'x_1': 1.0, 'x_2': 0.0, 'x_3': 0.8, 'x_4': 0.0, 'x_5': 0.0, 'x_6': 0.0}`

NOTE: The line `m, x = Knapsack(data1, 18)` resets the model `m` to the LP relaxation. All constraints from branching have to be added each time.

Q17: Use the following cell to compute the optimal value for the other node you found in **Q16**.

B [12]:
```
# TODO: Answer Q17
m, x = Knapsack(data, 18)
m.Add(x[2] >= 1)
solve(m)
```

```
Objective = 60.0
iterations : 0
branch-and-bound nodes : 0
```

Out[12]:
```
{'x_1': 0.6000000000000001,
 'x_2': 1.0,
 'x_3': 0.0,
 'x_4': 0.0,
 'x_5': 0.0,
 'x_6': 0.0}
```

Q18: What was the optimal value? Can this node be fathomed? Why? (Hint: In **Q13**, you found a feasible integer solution with value 64.)

A:

```
This node can be fathomed because the objective value is less than a
feasible integer solution with value 64 found in Q13.
```

If we continue running the branch and bound algorithm, we will eventually reach the branch and bound tree below where the z^* indictes the current node we are looking at.
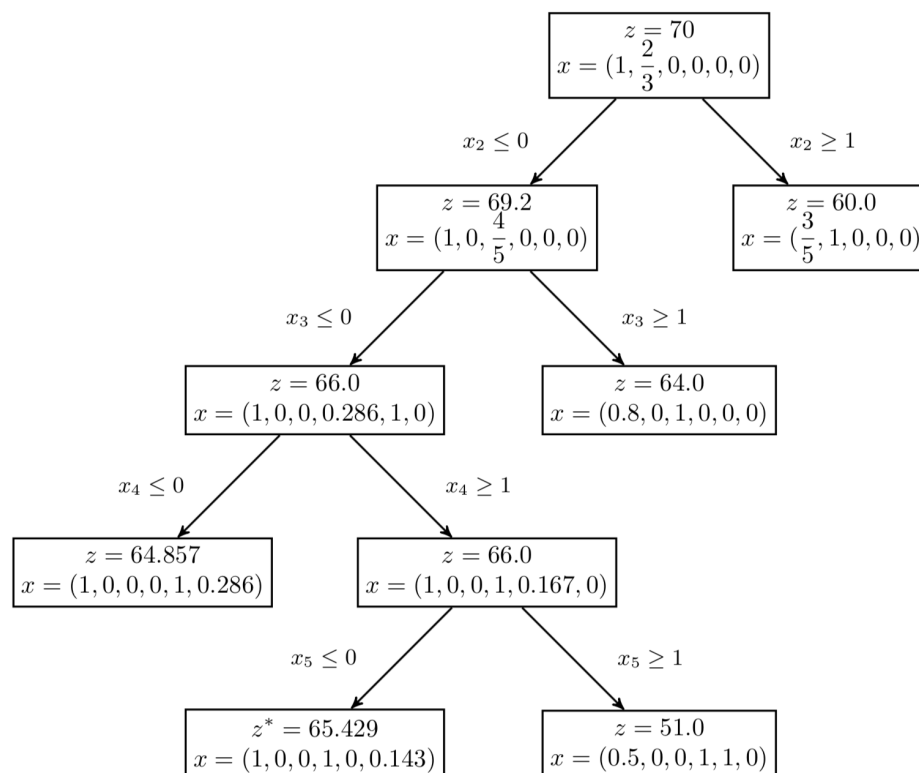

Q19: The node with $z = 64.857$ was fathomed. Why are we allowed to fathom this node? (Hint: think back to **Q3**)

A:

> We are allowed to fathom this node because no better solution could be
> found there

Q20: Finish running branch and bound to find the optimal integer solution. Use a separate cell for each node you solve and indicate if the node was fathomed with a comment. (Hint: Don't forget to include the constraints further up in the branch and bound tree.)

B [14]:
```python
# Template
m, x = Knapsack(data, 18)

# Add constraints here
m.Add(x[2] <= 0)
m.Add(x[3] <= 0)
m.Add(x[4] >= 1)
m.Add(x[5] <= 0)

m.Add(x[6] <= 0)

solve(m)
# fathomed? no
```

```
Objective = 64.0
iterations : 0
branch-and-bound nodes : 0
```

Out[14]: {'x_1': 1.0, 'x_2': 0.0, 'x_3': 0.0, 'x_4': 1.0, 'x_5': 0.0, 'x_6': 0.0}

B [15]:
```python
# Template
m, x = Knapsack(data, 18)

# Add constraints here
m.Add(x[2] <= 0)
m.Add(x[3] <= 0)
m.Add(x[4] >= 1)
m.Add(x[5] <= 0)

m.Add(x[6] >= 1)

solve(m)
# fathomed? yes
```

```
Objective = 44.0
iterations : 0
branch-and-bound nodes : 0
```

Out[15]: {'x_1': 0.4, 'x_2': 0.0, 'x_3': 0.0, 'x_4': 1.0, 'x_5': 0.0, 'x_6': 1.0}

B [ ]:

A:

Q21: How many nodes did you have to explore while running the branch and bound algorithm?

A:

```
11 nodes
```

In the next section, we will think about additional constraints we can add to make running branch and bound quicker.

Part 3: Cutting Planes

In general, a cutting plane is an additional constraint we can add to an integer program's linear relaxation that removes feasible linear solutions but does not remove any integer feasible solutions. This is very useful when solving integer programs! Recall many of the problems we have learned in class have something we call the "integrality property". This is useful because it allows us to ignore the integrality constraint since we are garunteed to reach an integral solution. By cleverly adding cutting planes, we strive to remove feasible linear solutions (without removing any integer feasible solutions) such that the optimal solution to the linear relaxation is integral!

Conisder an integer program whose linear program releaxation is

$$
\begin{aligned}
\max \quad & 2x_1 + x_2 \\
\text{s.t.} \quad & x_1 + x_2 \leq 3 \\
& 2x_1 \leq 5 \\
& -x_1 + 2x_2 \leq 2 \\
& x_1, x_2 \geq 0
\end{aligned}
$$

We can define this linear program and then visualize its feasible region. The integer points have been highlighted.

```
B [16]:  lp = gilp.LP([[1,1],[2,0],[-1,2]],
                       [3,5,2],
                       [2,1])
         fig = gilp.lp_visual(lp)
         fig.set_axis_limits([3.5,2])
         fig.add_trace(feasible_integer_pts(lp, fig))
         fig
```

Geometric Interpretation of LPs

Constraint(s)
- (3) $1x_1 + 1x_2 \leq 3$
- (4) $2x_1 + 0x_2 \leq 5$
- (5) $-1x_1 + 2x_2 \leq 2$
Q22: List every feasible solution to the integer program.

A:

```
(0,0), (1,0), (2,0), (0,1), (1,1), (2,1)
```

Q23: Is the constraint $x_2 \leq 1$ a cutting plane? Why? (Hint: Would any feasible integer points become infeasible? What about feasible linear points?)

A:

```
Yes, the constraint x2<= 1 is a cutting plane because it removes feasible
linear solutions but does not remove any integer feasible solutions.
```

Let's add this cutting plane to the LP relaxation!

```
B [17]:  lp = gilp.LP([[1,1],[2,0],[-1,2],[0,1]],
                       [3,5,2,1],
                       [2,1])
         fig = gilp.lp_visual(lp)
         fig.set_axis_limits([3.5,2])
         fig.add_trace(feasible_integer_pts(lp, fig))
         fig
```

Geometric Interpretation of LPs

Constraint(s)
- (3) $1x_1 + 1x_2 \leq 3$
- (4) $2x_1 + 0x_2 \leq 5$
- (5) $-1x_1 + 2x_2 \leq 2$
- (6) $0x_1 + 1x_2 \leq 1$
Q24: Is the constraint $x_1 \leq 3$ a cutting plane? Why?

A:

```
No, it is not a cutting plane because it does not remove any linear
feasible solutions
```

Q25: Can you provide another cutting plane? If so, what is it?

A:

```
Another cutting plane is x1<=2
```

Let's look at the feasible region after adding the cutting plane from **Q23** and one of the possible answers from **Q25**. Notice the optimal solution to the LP relaxation is now integral!

B [18]:
```
lp = gilp.LP([[1,1],[2,0],[-1,2],[0,1],[1,0]],
             [3,5,2,1,2],
             [2,1])
fig = gilp.lp_visual(lp)
fig.set_axis_limits([3.5,2])
fig.add_trace(feasible_integer_pts(lp, fig))
fig
```

Geometric Interpretation of LPs
Let's try applying what we know about cutting planes to the knapsack problem! Again, recall our input was $W = 18$ and:

B [19]: `data`

Out[19]:

item	value	weight	value per unit weight
1	50	10	5.00
2	30	12	2.50
3	24	10	2.40
4	14	7	2.00
5	12	6	2.00
6	10	7	1.43

Q26: Look at items 1, 2, and 3. How many of these items can we take simultaneously? Can you write a new constraint to capture this? If so, please provide it.

A:

```
We can only take one of these items simultaneously. x1 + x2 + x3 <= 1
```

Q27: Is the constraint you found in **Q26** a cutting plane? If so, provide a feasible solution to the linear program relaxation that is no longer feasible (i.e. a point the constraint *cuts off*).

A:

```
Yes, the constraint found in Q26 is a cutting plane. x1 = 1 and x2 =
0,6666667 is no longer feasible
```

Q28: Provide another cutting plane involving items 4,5 and 6 for this integer program. Explain how you derived it.

A:

```
x4 + x5 + x6 <= 2.
Simultaneously we can only 2 out of these 3 items without vioaliting the
weight constraint.
```

Q29: Add the cutting planes from **Q26** and **Q28** to the model and solve it. You should get a solution in which we take items 1 and 4 and $\frac{1}{6}$ of item 5 with an objective value of 66.

```
B [20]: m, x = Knapsack(data, 18)
        # TODO: Add cutting planes here
        m.Add(x[1] + x[2] + x[3] <= 1)
        m.Add(x[4] + x[5] + x[6] <= 2)

        solve(m)
```

```
Objective = 66.0
iterations : 0
branch-and-bound nodes : 0
```

Out[20]: {'x_1': 1.0,
          'x_2': 0.0,
          'x_3': 0.0,
          'x_4': 1.0,
          'x_5': 0.16666666666666696,
          'x_6': 0.0}

Let's take a moment to pause and reflect on what we are doing. Recall from **Q9-11** that we dropped item 7 becuase its weight was greater than the capcity of the knapsack. Essentially we added the constraint $x_7 \leq 0$. This constraint was a cutting plane! It eliminated some linear feasible solutions but no integer ones. By adding these two new cutting planes, we can get branch and bound to terminate earlier yet again! So far, we have generated cutting planes by inspection. However, there are more algorithmic ways to identify them (which we will ignore for now).

If we continue running the branch and bound algorithm, we will eventually reach the branch and bound tree below where the z^* indictes the current node we are looking at.

$$z = 66.0$$
$$x = (1, 0, 0, 1, 0.167, 0)$$

$x_5 \leq 0$ $x_5 \geq 1$

$$z = 65.429$$
$$x = (1, 0, 0, 1, 0, 0.1428)$$

$$z^* = 66.0$$
$$x = (1, 0, 0, 0.286, 1, 0)$$

$x_6 \leq 0$ $x_6 \geq 1$

$$z = 64.0$$
$$x = (1, 0, 0, 1, 0, 0)$$

$$z = 62.0$$
$$x = (1, 0, 0, 0.142, 0, 1)$$
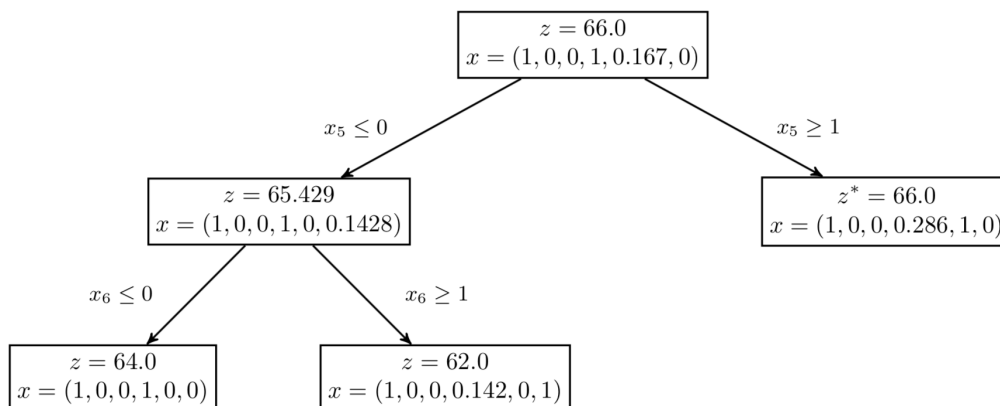

NOTE: Do not forget about the feasible integer solution our heuristic gave us with value 64.

Q30 Finish running branch and bound to find the optimal integer solution. Use a separate cell for each node you solve and indicate if the node was fathomed with a comment. Hint: Don't forget the cutting plane constraints should be included in every node of the branch and bound tree.

B [24]:
```python
# Template
m, x = Knapsack(data, 18)
# Add constraints here
m.Add(x[1] + x[2] + x[3] <= 1)
m.Add(x[4] + x[5] + x[6] <= 2)
m.Add(x[5] >= 1)
m.Add(x[4] <= 0)

solve(m)
# fathomed? no
```

```
Objective = 64.85714285714286
iterations : 0
branch-and-bound nodes : 0
```

Out[24]:
```
{'x_1': 1.0,
 'x_2': 0.0,
 'x_3': 0.0,
 'x_4': 0.0,
 'x_5': 1.0,
 'x_6': 0.28571428571428586}
```

B [25]:
```python
# Template
m, x = Knapsack(data, 18)
# Add constraints here
m.Add(x[1] + x[2] + x[3] <= 1)
m.Add(x[4] + x[5] + x[6] <= 2)
m.Add(x[5] >= 1)
m.Add(x[4] >= 1)

solve(m)
# fathomed? yes
```

```
Objective = 51.0
iterations : 0
branch-and-bound nodes : 0
```

Out[25]: `{'x_1': 0.5, 'x_2': 0.0, 'x_3': 0.0, 'x_4': 1.0, 'x_5': 1.0, 'x_6': 0.0}`

B [27]:
```python
# Template
m, x = Knapsack(data, 18)
# Add constraints here
m.Add(x[1] + x[2] + x[3] <= 1)
m.Add(x[4] + x[5] + x[6] <= 2)
m.Add(x[5] >= 1)
m.Add(x[4] <= 0)
m.Add(x[6] <= 0)

solve(m)
# fathomed? yes
```

```
Objective = 62.0
iterations : 0
branch-and-bound nodes : 0
```

Out[27]: {'x_1': 1.0, 'x_2': 0.0, 'x_3': 0.0, 'x_4': 0.0, 'x_5': 1.0, 'x_6': 0.0}

B [28]:
```python
# Template
m, x = Knapsack(data, 18)
# Add constraints here
m.Add(x[1] + x[2] + x[3] <= 1)
m.Add(x[4] + x[5] + x[6] <= 2)
m.Add(x[5] >= 1)
m.Add(x[4] <= 0)
m.Add(x[6] >= 1)

solve(m)
# fathomed? yes
```

```
Objective = 47.0
iterations : 0
branch-and-bound nodes : 0
```

Out[28]: {'x_1': 0.5, 'x_2': 0.0, 'x_3': 0.0, 'x_4': 0.0, 'x_5': 1.0, 'x_6': 1.0}

A:

Q31: Did you find the same optimal solution? How many nodes did you explore? How did this compare to the number you explored previously?

A:

```
Yes, I found the same optimal solution with exploring 9 nodes, which is
less than the number we explored previously.
```

Part 4: Geometry of Branch and Bound

Previously, we used the `gilp` package to viusualize the simplex algorithm but it also has the functionality to visualize branch and bound. We will give a quick overview of the tool. Similar to `lp_visual` and `simplex_visual`, the function `bnb_visual` takes an `LP` and returns a

visualization. It is assumed that every decision variable is constrained to be integer. Unlike previous visualizations, `bnb_visual` returns a series of figures for each node of the branch and bound tree. Let's look at a small 2D example:

$$\begin{aligned} \max \quad & 5x_1 + 8x_2 \\ \text{s.t.} \quad & x_1 + x_2 \le 6 \\ & 5x_1 + 9x_2 \le 45 \\ & x_1, x_2 \ge 0, \quad \text{integral} \end{aligned}$$

B [29]: ```
nodes = gilp.bnb_visual(gilp.examples.STANDARD_2D_IP)
```

B [30]: ```
nodes[0].show()
```

Geometric Interpretation of LPs
Run the cells above to generate a figure for each node and view the first node. At first, you will see the LP relaxation on the left and the root of the branch and bound tree on the right. The simplex path and isoprofit slider are also present.

Q32: Recall the root of a branch and bound tree is the unaltered LP relaxation. What is the optimal solution? (Hint: Use the objective slider and hover over extreme points).

A:

```
The optimal integer solution is x1 = 4 and x2 = 3 with z = 36
```

Q33: Assume that we always choose the variable with the minimum index to branch on if there are multiple options. Write down (in full) each of the LPs we get after branching off the root node.

A:

```
After branching x1, we get two additional nodes
    - with x1<=2:  z = 41.111 and (2,3.889)
    - with x1 >= 3 z = 39 and (3, 3)
```

Q34: Draw the feasible region to each of the LPs from **Q33** on the same picture.

A:

Run the following cell to see if the picture you drew in **Q34** was correct.

B [33]: `nodes[1].show()`

Geometric Interpretation of LPs
The outline of the original LP relaxation is still shown on the left. Now that we have eliminated some of the fractional feasible solutions, we now have 2 feasible regions to consider. The darker one is the feasible region associated with the current node which is also shaded darker in the branch and bound tree. The unexplored nodes in the branch and bound tree are not shaded in.

Q35: Which feasible solutions to the LP relaxation are removed by this branch?

A:

> Solutions with x1 >2

Q36: At the current (dark) node, what constraints will we add? How many feasible regions will the original LP relaxation be broken into?

A:

> Add x2<=3 and x2>=4 which breaks the original LP relaxation into three regions.

B [34]: `nodes[2].show()`

Geometric Interpretation of LPs
Q37: What is the optimal solution at the current (dark) node? Do we have to further explore this branch? Explain.

A:

```
x1 = 2 and x2 = 3, with obj value = 34. No we do not need to further
explore this branch because it will only become smaller.
```

Q38: Recall shaded nodes have been explored and the node shaded darker (and feasible region shaded darker) correspond to the current node and its feasible region. Nodes not shaded have not been explored. How many nodes have not yet been explored?

A:

```
2 nodes
```

Q39: How many nodes have a degree of one in the branch and bound tree? (That is, they are only connected to one edge). These nodes are called leaf nodes. What is the relationship between the leaf nodes and the remaining feasible region?

A:

```
3 leaf nodes
```

B [35]:
```
# Show the next two iterations of the branch and bound algorithm
nodes[3].show()
nodes[4].show()
```

Q40: At the current (dark) node, we added the constraint $x_1 \leq 1$. Why were the fractional solutions $1 < x_1 < 2$ not eliminated for $x_2 <= 3$?

A:

```
Because constraint x1 <= 1 is not yet introduced
```

B [36]:
```
# Show the next three iterations of the branch and bound algorithm
nodes[5].show()
nodes[6].show()
nodes[7].show()

Q41: What constraints are enforced at the current (dark) node? Why are there no feasible solutions at this node?

A:

```
x1<=2 and x2>=4 and x1>=2. There are no feasible solutions at this node
because two constraints contradict to each other: x1<=2 and x1>=2
```

B [37]:
```
nodes[8].show()
```

Geometric Interpretation of LPs
Q42: Are we done? If so, what nodes are fathomed and what is the optimal solution? Explain.

A:

```
Yes, we are done. Nodes with obj value 37, 34, and 39 are fathomed since
no better solutions could be found there.
```

Let's look at branch and bound visualization for an integer program with 3 decision variables!

B [38]:
```
nodes = gilp.bnb_visual(gilp.examples.VARIED_BRANCHING_3D_IP)
```

Q43: Consider the feasible region that looks like a rectangular box with one corner point at the origin. What node does it correspond to in the tree? What is the optimal solution at that node?

A:

```
This region correspond to the nodde with obj value of 12
```

Q44: How many branch and bound nodes did we explore? What was the optimal solution? How many branch and bound nodes would we have explored if we knew the value of the optimal solution before starting branch and bound?

A:

```
We explore 13 branch and bound nodes. The optimal solution is x1=0, x2=3,
x3=1, with z = 13. Only 2.
```

Bonus: Branch and Bound for Knapsack

Consider the following example:

item	value	weight
1	2	1
2	9	3
3	6	2

The linear program formulation will be:

$$\begin{aligned} \max \quad & 2x_1 + 9x_2 + 6x_3 \\ \text{s.t.} \quad & 1x_1 + 3x_2 + 2x_3 \leq 10 \\ & x_1, x_2, x_3 \geq 0, \quad \text{integer} \end{aligned}$$

In gilp, we can define this lp as follows:

B [42]:
```
lp = gilp.LP([[1,3,2]],
             [10],
             [2,9,6])

for fig in gilp.bnb_visual(lp):
    fig.show()
```
